## S Supporting Information

**ABSTRACT:** Estrogen receptor  $\beta$  (ER $\beta$ ) selective agonists are considered potential therapeutic agents for a variety of pathological conditions, including several types of cancer. Their development is particularly challenging, since differences in the ligand binding cavities of the two ER subtypes  $\alpha$  and  $\beta$  are minimal. We have carried out a rational design of new salicylketoxime derivatives which display unprecedentedly high levels of ER $\beta$  selectivity for this class of compounds, both in binding affinity and in cell-based functional assays. An endogenous gene expression assay was used to further characterize the pharmacological action of these compounds. Finally, these ER $\beta$ -selective agonists were found to inhibit proliferation of a glioma cell line in vitro. Most importantly, one of these compounds also proved to be active in an in vivo xenograft model of human glioma, thus demonstrating the high potential of this type of compounds against this devastating disease.

## INTRODUCTION

Estrogen receptors (ERs) are nuclear transcription factors that mediate the physiological functions of estrogenic compounds. These receptors exert many of their actions in the nucleus, where they bind to associated DNA regulatory sequences and modulate the transcription of specific target genes. Two ER subtypes,  $\alpha$  (ER $\alpha$ ) and  $\beta$  (ER $\beta$ ), are known,<sup>1</sup> and subsequent studies have indicated the presence of up to five different ER $\beta$  isoforms (ER $\beta$ 1–5) that arise from alternative splicing of the last exon coding for ER $\beta$ .<sup>2</sup> Nevertheless, the only fully functional ER $\beta$  isoform appears to be the originally cloned 59 kDa ER $\beta$ 1 isoform; hence, this is the isoform referred to simply as ER $\beta$ .

Both ER $\alpha$  and ER $\beta$  are widely distributed throughout the human body, where they modulate biological functions in several organ systems. In addition to their obvious control of the female reproductive system, they also play key roles in skeletal, cardiovascular, and central nervous systems. ER $\alpha$  plays a more prominent role in the mammary gland and uterus, on the preservation of bone homeostasis, and on the regulation of metabolism. ER $\beta$  has more pronounced effects on the central nervous system (CNS) and immune system. Moreover, the  $\beta$ -

subtype generally counteracts the ER $\alpha$ -promoted cell hyperproliferation in tissues such as breast and uterus and is generally considered a tumor suppressor in these organs. This antiproliferative effect exerted by ER $\beta$  was also observed in several cancer tissues, such as, for example, breast,<sup>3</sup> prostate,<sup>4</sup> colon,<sup>5</sup> renal,<sup>6</sup> pleural mesothelioma,<sup>7</sup> and glioma.<sup>8</sup> In particular, the protective role of ER $\beta$  in gliomas is also supported by the fact that the incidence of developing this type of cancer is smaller in women than in men,<sup>9</sup> and the use of exogenous estrogens further reduces this incidence.<sup>10</sup> All this evidence suggests that selective activation of this receptor subtype may be exploited in order to obtain an antitumor effect.

Several efforts have been dedicated so far to the development of ER $\alpha$ - or ER $\beta$ -selective ligands.<sup>11</sup> In particular, a great deal of attention has been focused on ER $\beta$ -selective agonists,<sup>12</sup> which have the potential to be used as antitumor agents because they predominantly activate the  $\beta$ -subtype, thus being free from the undesired ER $\alpha$ -promoted proliferative effects on breast and uterus. However, this endeavor is particularly difficult since, in

spite of a limited overall sequence identity (59%) in the ligand binding domains (LBD) of the two subtypes, the differences within the ligand binding cavities are at only two amino acid positions and consist of minor changes between hydrophobic residues. Thus, Leu384 and Met421 in ER $\alpha$  are replaced by Met336 and Ile373, respectively, in ER $\beta$ . A more important difference arises from the smaller volume of ER $\beta$  binding pocket when compared to that of ER $\alpha$ , which may be exploited in the design of ER $\beta$ -selective ligands.

We have been involved in the optimization of selective ER $\beta$  agonists that were developed by structural refinements of a monoaryl-substituted salicylaldoxime scaffold.<sup>13</sup> In this article we describe how molecular modeling has indicated a simple way to introduce molecular variations that produced some salicylketoxime derivatives displaying significant improvements in binding affinity, transactivation activity, and subtype selectivity over their aldoxime counterparts. Furthermore, for the first time further pharmacological evaluations were conducted on our oxime-based ER $\beta$ -agonists, both in vitro, on a glioma U87 cell line, and in vivo on a murine xenograft model of the same tumor.

## RESULTS AND DISCUSSION

**Molecular Modeling and Design.** Some of the most potent and selective salicylaldoxime-based ER $\beta$ -selective agonists were obtained by interchanging the respective positions of the hydroxyl and oxime groups of the Salalox A class, to produce compounds belonging to the Salalox B class (Figure 1).<sup>13c</sup> We then decided to further analyze the complex derived by a docking procedure of the simplest member of the Salalox B class, compound **1** (Figure 1), into ER $\beta$ -binding cavity, in order to search for additional productive interactions

**Figure 1.** General structures of Salalox A and Salalox B compounds; position of the hydrophobic cavity in the complex of aldoxime **1** into ER $\beta$ ; design of new ketoxime derivatives containing a methyl (**2a**), an ethyl (**2b**), or a trifluoromethyl (**2m**) group.

that might enhance ER $\beta$  binding affinity or selectivity. From this modeling analysis we realized that there is an empty hydrophobic cavity that abuts the aldoxime hydrogen atom and is delimited by Phe356 and Leu301 (Figure 1 and Figure 2A). Therefore, we decided to fill this cavity with a suitable small lipophilic group, such as a methyl, an ethyl, or a trifluoromethyl substituent so that the binding affinity of the resulting compounds could be improved. A similar docking analysis of a methyl-ketoxime analogue of **1**, such as compound **2a** (Figure 1), showed that this compound nicely fits into the receptor binding site and neatly places its methyl group in the lipophilic cavity (Figure 2B). It should be noted that the presence of the ketoxime portion slightly distorts the pseudocycle, which is formed because of the intramolecular H-bond of these oxime derivatives. This is due to the larger steric interaction of the methyl group compared to a hydrogen atom with the adjacent arene C–H bond. Nevertheless, the most important interactions that are typical of these types of ER $\beta$  ligands<sup>13c</sup> are maintained: in detail, both **1** and **2a** have their oxime OH group participating in a highly energetic H-bond network with residues Glu305 and Arg346, and their antipodal phenolic OH group forms another H-bond with Thr299 (Figure 2A and Figure 2B).

In light of these theoretical results, we planned the synthesis of a selected series of methyl-, ethyl-, and trifluoromethyl-ketoximes (**2a–m**, Chart 1), where we could also investigate the effect due to the variation of the substitution pattern in the aryl substituent ( $R^2$ , Chart 1). In particular, we wanted to verify whether the addition of an extra substituent (F, Cl, or  $\text{CH}_3$ ) in the 3-position or the replacement of the phenol 4-OH with a group that is exclusively able to act as a H-bond acceptor ( $\text{OCH}_3$ , F, Cl) could lead to any further improvement of ER $\beta$  affinity and selectivity. In fact, that portion of the molecules binds to the OH group of a threonine residue (Thr299) of the receptor, which may act as a H-bond donor or acceptor. In fact, compounds possessing a *p*-OH group (**2a–d**, **2i**, **2k**, **2m**,  $R^2 = \text{OH}$ ; Chart 1) are likely to mainly donate a H-bond to Thr299, whereas the others (**2e–h**, **2j**, **2l**,  $R^2 = \text{OCH}_3$ , F, Cl; Chart 1) can only function as H-bond acceptors in their interaction with the same residue. It should be noted that oximes **2a–l** were obtained as single (*E*)-diastereoisomers, whereas trifluoromethyl-substituted oxime **2m** could only be obtained as a (*E/Z*)-diastereoisomeric mixture (see discussion below).

**Chemistry.** The synthesis of methyl- and ethyl-ketoximes **2a–l** followed a common, straightforward reaction sequence, starting from commercially available 5-bromo-2-hydroxyacetophenone (**3**) or 5-bromo-2-hydroxypropiophenone (**4**), respectively (Scheme 1). The first step involved a Pd-catalyzed cross-coupling reaction under classical Suzuki conditions.<sup>14</sup> In detail, compounds **3** and **4** were treated with 1.2 equiv of the appropriate arylboronic acid in the presence of aqueous sodium carbonate and a solvent mixture composed of toluene/ethanol (1:1). Catalyst  $\text{Pd}(\text{PPh}_3)_4$  was formed in situ by reaction of palladium acetate with a 5-fold excess of triphenylphosphine. Conventional heating at 100 °C overnight produced the desired aryl-substituted acetophenone (**5e–h**, **5j**, **5l**) and propiophenone (**6**, **7**) derivatives in good yields. Ketoxime containing methoxy- or halogen-substituted aryl rings (**2e–h**, **2j**, **2l**) were then obtained by a direct condensation with hydroxylamine hydrochloride. On the other hand, an intermediary  $\text{BBr}_3$ -promoted deprotection of compounds **5e**, **5f**, **5j**, **5l**, **6**, and **7** was needed to produce hydroxyaryl-substituted ketoximes (**2a–d**, **2i**, **2k**), via the initial formation of ketones (**8a–d**, **8i**, **8k**)

**Figure 2.** Docking analysis of salicylaldoxime **1** (A) and salicylketoexime **2a** (B) into ER $\beta$  binding site. The volume of the small hydrophobic cavity is represented in yellow (PDB code of the starting ER $\beta$  crystal structure is 2IOG).

<sup>a</sup>Reagents and conditions: (a)  $\text{ArB}(\text{OH})_2$  (1.2 equiv),  $\text{Pd}(\text{OAc})_2$  (0.04 equiv),  $\text{PPh}_3$  (0.2 equiv), aqueous 2 M  $\text{Na}_2\text{CO}_3$ , 1:1 toluene/EtOH, 100 °C, 16 h; (b)  $\text{NH}_2\text{OH}\cdot\text{HCl}$ , EtOH– $\text{H}_2\text{O}$ , 50 °C, 16 h; (c)  $\text{BBr}_3$ ,  $\text{CH}_2\text{Cl}_2$ , –78 to 0 °C, 1 h.

followed by final condensation with hydroxylamine hydrochloride.

As previously observed for structurally related salicylaldoxime derivatives,<sup>13</sup> all methyl- and ethyl-ketoeximes obtained in this manner possess the *E*-configuration in their oxime portion, which is also consistent with the high degree of stabilization induced by the energetic intramolecular H-bond between the oxime nitrogen atom and the adjacent OH group. These configurations were demonstrated by  $^1\text{H}$  and  $^{13}\text{C}$  NMR analysis of the final compounds **2a–l**. In the case of the methyl-ketoeximes (**2a**, **2c**, **2e–l**), the  $^1\text{H}$  NMR chemical shift values ( $\delta$ ) of the methyl protons ( $2.44 \leq \delta \leq 2.46$  ppm) closely correspond to the values reported in the literature for the *E*-isomer of analogous aromatic methyl-ketoeximes.<sup>15</sup> Moreover, the most significant results are given by the  $^{13}\text{C}$  NMR chemical shift values of the methyl carbon atom ( $10.80 \leq \delta \leq 10.87$  ppm), which nicely overlaps with the values observed for the *E*-isomer of previously reported aromatic methyl-ketoeximes ( $11.5 \leq \delta \leq 12.4$  ppm) and which differs substantially from the values reported for the *Z*-isomers ( $21 \leq \delta \leq 21.4$  ppm).<sup>16</sup> By analogy, an *E*-configuration was assigned to ethyl-ketoeximes **2b,d**.

The synthesis of trifluoromethyl-ketoexime **2m** required a different reaction sequence starting from commercially available 5-bromo-2-methoxybenzaldehyde (**9**), as shown in Scheme 2. We followed a trifluoromethylation/oxidation protocol,<sup>17</sup> which had already been applied to the synthesis of trifluoromethylketone **11**, via the isolation of intermediate trifluoromethylcarbinol **10**.<sup>18</sup> Subsequent Pd-catalyzed cross-coupling reaction of bromoaryl **11** with 4-methoxyphenylboronic acid produced biphenyl derivative **12**, which was deprotected with  $\text{BBr}_3$ . The resulting dihydroxylated trifluoromethylketone **13** was then condensed with hydroxylamine hydrochloride, thus affording the final product **2m**.

In distinction with the ketoeximes **2a–l**, which were obtained as single (*E*)-diastereoisomers, the trifluoromethylketoexime **2m** was obtained as an 8:2 *E/Z*-diastereoisomeric mixture (note that in **2m** there is a nominal inversion of the *E/Z*-diastereoisomers). Assignment of the (*E*)-geometry to the most abundant isomer is based on a comparison of the NMR signals with a 2-hydroxyaryl-substituted trifluoromethylketoexime, which was characterized by crystallographic X-ray analysis.<sup>19</sup> In fact,  $^{13}\text{C}$  NMR spectra of **2m** display peaks of

<sup>a</sup>Reagents and conditions: (a) TMS- $\text{CF}_3$ , TBAF, THF, rt, 10 h; then HCl (4.4 M), rt, 1 h; (b) TEMPO,  $\text{PhI}(\text{OAc})_2$ ,  $\text{CH}_2\text{Cl}_2$ , rt, 13 h; (c) 4-methoxyphenylboronic acid (1.2 equiv),  $\text{Pd}(\text{OAc})_2$  (0.04 equiv),  $\text{PPh}_3$  (0.2 equiv), aqueous 2 M  $\text{Na}_2\text{CO}_3$ , 1:1 toluene/EtOH, 100 °C, 16 h; (d)  $\text{BBr}_3$ ,  $\text{CH}_2\text{Cl}_2$ , -78 to 0 °C, 1 h; (e)  $\text{NH}_2\text{OH}\cdot\text{HCl}$ , EtOH- $\text{H}_2\text{O}$ , 50 °C, 16 h.

the major isomer corresponding to the  $\text{CF}_3$  at 122.23 (quartet,  $^1J_{\text{C-F}} = 273.0$  Hz) and to the oxime carbon atom at 146.23 (quartet,  $^2J_{\text{C-F}} = 33.0$  Hz), which compare favorably to the corresponding peaks reported in the literature for the (*E*)-isomer of 1-(2,4-dihydroxy-3,5-dipropylphenyl)-2,2,2-trifluoroethanone oxime: 123.1 (quartet,  $^1J_{\text{C-F}} = 274.5$  Hz), 148.3 (quartet,  $^2J_{\text{C-F}} = 27.9$  Hz).<sup>19</sup> This peculiar outcome of the condensation reaction of trifluoromethyl-ketone **13** with hydroxylamine is probably dictated by the substantial stereoelectronic repulsion that takes place when the OH and  $\text{CF}_3$  groups are placed on the same side, as in the (*Z*)-isomer (Figure 3).

**Figure 3.** Stereoelectronic repulsion occurring in the (*Z*)-diastereoisomer of **2m**, which favors the formation of (*E*)-**2m**.

Unfortunately, we were not able to separate the two isomers, and therefore, compound **2m** was submitted as a 8:2 (*E/Z*)-diastereoisomeric mixture to the receptor binding assays reported below.

**Biological Evaluation.** The binding affinity of ketoximes **2a–l** for  $\text{ER}\alpha$  and  $\text{ER}\beta$  was measured by a radiometric competitive binding assay by using previously reported methods.<sup>20,21</sup> The relative binding affinity (RBA) values for the newly reported compounds, together with that previously obtained for reference aldoxime **1**,<sup>13b</sup> are summarized in Table 1. RBA values are reported as percentage (%) of that of estradiol, which is set at 100%.

The most important finding from these binding measurements is the confirmation of our initial hypothesis derived from the computer-aided drug design. In fact, when a methyl group is inserted onto the oxime portion of aldoxime **1**, a general improvement of the binding affinity of the resulting ketoxime **2a** is observed, which is particularly evident for  $\text{ER}\beta$ . In fact, **2a** displays a 17-fold improvement in  $\text{ER}\beta$ -binding affinity and a 2-

<sup>a</sup>Determined by a competitive radiometric binding assay with [ $^3\text{H}$ ]estradiol. Preparations of purified, full-length human  $\text{ER}\alpha$  and  $\text{ER}\beta$  (PanVera) were used; see Experimental Section. Values are reported as the mean  $\pm$  the range or SD of two or more independent experiments. The  $K_d$  of estradiol for  $\text{ER}\alpha$  is 0.2 nM and for  $\text{ER}\beta$  is 0.5 nM.  $K_i$  values for the new compounds can be readily calculated by using the formula  $K_i = (K_d[\text{estradiol}]/\text{RBA}) \times 100$ . <sup>b</sup>See ref 13b.

fold improvement in  $\text{ER}\beta$ -selectivity over its nonmethylated counterpart **1**. It should be noted that the  $\text{ER}\beta$ -RBA value of 45.7% observed for **2a** corresponds to a  $K_i$  of 1.1 nM, thus confirming the remarkably high affinity of this compound for the  $\beta$ -subtype. An enlargement of the oxime alkyl substituent, from a methyl to an ethyl group, produces a compound (**2b**), which preserves an excellent affinity for  $\text{ER}\beta$  but also gains some affinity for  $\text{ER}\alpha$ , thus resulting in an  $\text{ER}\beta$  selectivity that is less than that of **2a**. The introduction of a *m*-fluorine atom into the 4-hydroxyphenyl group of compounds **2a** and **2b**, respectively, produced compounds **2c** and **2d**, which did not display any significant improvements over their nonfluorinated counterparts. Rather, a marked loss of affinity for  $\text{ER}\beta$  was observed for methyl-ketoxime **2c**. Furthermore, when a *m*-methyl group (**2i**) or a *m*-chlorine atom (**2k**) was analogously inserted in the structure of **2a**, an even more dramatic reduction of the binding to  $\text{ER}\beta$  was observed. As previously observed for other oxime derivatives,<sup>13</sup> the presence of a *p*-methoxy group into the aryl substituent of these ketoxime derivatives always compromises the receptor binding affinities of the resulting compounds (**2e**, **2f**, **2j**, and **2l**). On the other hand, the replacement of the *p*-hydroxy group with a fluorine (**2g**) or chlorine atom (**2h**) restores a certain, though minimal, affinity for  $\text{ER}\beta$ . Overall, these binding assays confirm that the  $\text{ER}\beta$  ligand cavity may profitably host methyl- (**2a**) and an ethyl- (**2b**) ketoxime portion, although the highest  $\beta$ -selectivity is obtained with the former, and that the 4-hydroxyphenyl substituent still constituted an ideal moiety for an efficient binding to  $\text{ER}\beta$ .

In order to evaluate the binding disposition of these derivatives in  $\text{ER}\alpha$ , the most interesting compounds **2a** and **2b** were also analyzed for their interaction with this receptor subtype (Figure 4). As already reported,<sup>13b</sup> the interaction of Thr299 with the 4'-hydroxyl of **2a** and **2b** is only possible in  $\text{ER}\beta$  because only in this subtype is there enough space for the phenol group to reach Thr299, because of its proximity to

**Figure 4.** Docking analysis of **2a** (A) and **2b** (B) into ER $\alpha$  (PDB code of the starting ER $\alpha$  crystal structure is 2IOJ).

**Figure 5.** Dose–response curves for transcriptional activation by estradiol (E2), **2a**, and **2c** through ER $\alpha$  (red line) and ER $\beta$  (green line) in the reporter gene transfection assay. Human endometrial cancer (HEC-1) cells were transfected with expression vectors for ER $\alpha$  or ER $\beta$  and an (ERE) $_2$ -pS2-luc reporter gene and were treated for 24 h with estradiol, **2a**, or **2c** at the concentrations indicated. Luciferase activity was expressed relative to  $\beta$ -galactosidase activity from an internal control plasmid. The maximal activity with 1 nM E2 was set at 100%. Values are the mean and SD of triplicate determinations.

**Table 2.** Reporter Gene Transfection Assay in Human Endometrial (HEC-1) Cells: Transcriptional Activities of Estradiol and Compounds **2a** and **2c**<sup>a</sup>

ligand	hER $\alpha$		hER $\beta$		EC $_{50}$ ( $\beta/\alpha$ ) ratio	RTP( $\beta/\alpha$ ) ratio
	EC $_{50}$ (nM)	RTP (%)	EC $_{50}$ (nM)	RTP (%)		
estradiol	0.16 $\pm$ 0.03	100	0.38 $\pm$ 0.09	100	0.42	1
<b>2a</b>	29.3 $\pm$ 7.6	0.546	3.97 $\pm$ 0.76	9.62	7.4	18
<b>2c</b>	194 $\pm$ 98.6	0.083	14.7 $\pm$ 5.2	2.59	13	31

<sup>a</sup>EC $_{50}$  values give absolute potencies. The ER $\beta$ /ER $\alpha$  relative transcriptional potencies (RTP) and ratios (RTP( $\beta/\alpha$ )) are calculated as explained in the text. Cells were exposed to the compounds for 24 h prior to measurements. See refs 22 and 23.

Met336, one of the two nonconserved residues that in ER $\alpha$  is replaced by bulkier Leu384. As shown in Figure 3, the docking results showed that for both compounds **2a** and **2b** the phenolic OH interacts in the ER $\alpha$  with the Glu305–Arg346–water hydrogen bonding system, the pseudocycle/oxime system does not show any important interactions, and the methyl (**2a**)/ethyl (**2b**) substituents show lipophilic interactions with Phe404, Phe425, and Leu428. This binding disposition is very similar to that hypothesized for compound **1**,<sup>13b</sup> and the lipophilic interactions of the methyl/ethyl group may explain the increase in ER $\alpha$  affinity associated with ketoximes **2a** and **2b**, when compared to that of aldoxime **1**. Nevertheless, the ER $\beta$ -binding affinities of **2a** increase to a larger extent (17-fold) when compared to its improvement in binding to ER $\alpha$  (8-fold), and therefore, the newly synthesized ketoxime **2a** display a substantial enhancement of both affinity and selectivity for ER $\beta$ .

The compounds showing the highest levels of  $\beta$ -selectivity in the receptor binding assays (**2a** and **2c**) were assayed for transcriptional activity through ER $\alpha$  and ER $\beta$  by two different methods, and estradiol was always used as the reference receptor activator. The first method was a reporter gene transfection assay, which was conducted in human endometrial (HEC-1) cells, using expression plasmids for either full-length human ER $\alpha$  or ER $\beta$  and an estrogen-responsive luciferase reporter gene system.<sup>22,23</sup> These assays (Figure 5, Table 2) showed that estradiol (E2) has a 2.4-fold preference in favor of ER $\alpha$  in terms of transcriptional potency (EC $_{50}$ [ER $\alpha$ ] = 0.16 nM vs EC $_{50}$ [ER $\beta$ ] = 0.38 nM), as has been widely noted. We had previously reported<sup>13b</sup> that aldoxime **1** is also a potent ER $\beta$  full agonist, with an EC $_{50}$  of 10 nM, but it also stimulated ER $\alpha$  with an EC $_{50}$  of 17 nM. New ketoxime **2a** displayed significant improvements over aldoxime **1**, in terms of both potency on ER $\beta$  (EC $_{50}$ [ER $\beta$ ] = 3.97 nM) and subtype-selectivity

**Table 3.** Activation of Endogenous Genes in Human Breast Cancer (MCF-7) Cells Containing Only ER $\alpha$  or Both ER $\alpha$  and ER $\beta$ : Transcriptional Activities of Estradiol and Compounds 2a and 2c<sup>a</sup>

<sup>a</sup>EC<sub>50</sub> values give absolute potencies. The ER $\beta$ /ER $\alpha$  relative transcriptional potencies (RTP) and ratios (RTP ( $\beta$ / $\alpha$ )) are calculated, as explained in the text. Cells were exposed to the compounds for 24 h prior to measurements. See refs 24–26.

**Figure 6.** Dose–response curves for transcriptional activation of endogenous genes by estradiol (E2), 2a, and 2c. The response of progesterone receptor (PR, red curves), a gene activated predominantly through ER $\alpha$ , and otubain 2 (OTUB2, green curves), a gene activated predominantly through ER $\beta$ , was measured by qPCR at 24 h after exposure of human breast cancer (MCF-7) cells containing only ER $\alpha$  (solid curves) or both ER $\alpha$  and ER $\beta$  (dashed curves) to compounds at the indicated concentrations. Values are the mean  $\pm$  SD of triplicate determinations. For details, see ref 24.

(EC<sub>50</sub>[ER $\alpha$ ] = 29.3 nM). Ketoxime 2c proved to suffer from a  $\sim$ 4-fold reduction in its potency on ER $\beta$  (EC<sub>50</sub>[ER $\beta$ ] = 14.7 nM) when compared to 2a, although an even more pronounced loss of activity on ER $\alpha$  (EC<sub>50</sub>[ER $\alpha$ ] = 194 nM) elevates its  $\beta$ -selectivity.

To compare the ER subtype transcriptional potencies of these compounds with their subtype binding affinities in a more proper way, we calculated their relative transcriptional potency (RTP) values from their EC<sub>50</sub> values according to the formula  $RTP = (EC_{50}^{(estradiol)} / EC_{50}^{(ligand)}) \times 100$  (RTP of estradiol = 100). These RTP values provide an estimate of transcriptional potency relative to that of estradiol and, therefore, are more appropriate to compare with their binding affinities, which are also measured relative to estradiol as RBA. By these metrics (Tables 1 and 2), compound 2a has an RBA( $\beta$ / $\alpha$ ) ratio of 84 and an RTP( $\beta$ / $\alpha$ ) ratio of 18, and compound 2c has an RBA( $\beta$ / $\alpha$ ) ratio of 72 and an RTP( $\beta$ / $\alpha$ ) ratio of 31. It is worth noting that differences in ER $\beta$ -selectivity in terms of transcriptional potency vs binding affinity may be ascribed to changes in the manner in which the ER $\alpha$ - and ER $\beta$ -ligand complexes interact with numerous cellular coregulators, which act as modulators of ligand potency. Therefore, when measured relative to estradiol, most of the ER $\beta$  affinity preference of these compounds is actually maintained in their ER $\beta$  transcriptional potency preference.

In addition to the reporter gene assays, we also examined the regulation of two endogenous genes, the progesterone receptor (PR), which is mostly activated through ER $\alpha$ , and otubain 2 (OTUB2), which is stimulated largely through ER $\beta$ .<sup>24–26</sup> We studied the activation of these genes in MCF-7 breast cancer cells containing either ER $\alpha$  only, or ER $\alpha$  and ER $\beta$  (Figure 5 and Table 3).

As we have observed before,<sup>24,25</sup> the PR gene (Figure 6, red curves) is effectively stimulated by estradiol (E2) in cells with

only ER $\alpha$  (solid red curve), with this stimulation being somewhat less in cells containing ER $\alpha$  and ER $\beta$  (dashed red curve). By contrast, the OTUB2 gene (green curves) requires the presence of ER $\beta$  (ER $\alpha$  plus ER $\beta$  cells, dashed green curve) to be stimulated effectively, the response being very minimal in cells with only ER $\alpha$  (solid green curve). The OTUB2 gene is also stimulated in ER $\alpha$  + ER $\beta$  cells with the two ER $\beta$ -selective ketoximes (2a and 2c; green dashed curves), though at a somewhat lowered potency, and as expected, no stimulation of OTUB2 with these compounds was seen in cells with only ER $\alpha$  (solid green curves). While there was some stimulation of PR by these compounds, this required high concentrations (the red curves were right shifted compared to that for E2; see also Table 3).

Again, as was the case with the reporter gene assays (Figure 5, Table 2), comparisons of potencies in transcription assays with binding affinities require that the EC<sub>50</sub> values from the transcription assay be referenced to the values of E2, expressed as RTP values (Table 3). Clearly, the RTP values of compounds 2a and 2c are far greater for the ER $\beta$ -mediated response (OTUB2 activation in ER $\alpha$  + ER $\beta$  cells) than the ER $\alpha$ -mediated response (PR activation in ER $\alpha$  only cells). The RTP ( $\alpha$  +  $\beta$ )/ $\alpha$  ratios, in particular, highlight the very high ER $\beta$  selectivity of these compounds.

We then wanted to evaluate a possible application of our most promising ER $\beta$  agonists as antitumor agents. Among the beneficial effects of estrogens, a possible protective role in the progression of gliomas has been reported.<sup>27</sup> In fact, this deadly disease has a significantly lower incidence in reproductive-aged females than in males. Recently, a naturally occurring ER $\beta$  agonist, liquiritigenin, was shown to be active in vitro against U87 glioma cells and also in a murine model of the same disease.<sup>8</sup> Therefore, we decided to test the ability of our best ketoximes 2a and 2c, together with aldoxime 1 and

**Table 4.** Effects on Cell Growth ( $IC_{50}$ ,  $\mu M$ ) of Human Glioma (U87), Colon (LoVo, HCT), and Breast (MDA-MB-231, MCF7, SkBr3) Cancer Cells by Compounds **1**, **2a**, and **2c** and Liquiritigenin<sup>a</sup>

compd	$IC_{50}$ ( $\mu M$ )

liquiritigenin, a major component in licorice root extracts, to block proliferation of glioma (U87), colon (LoVo, HCT), and breast (MDA-MB-231, MCF7, SKBR3) cancer cells. The results are reported in Table 4.

As for the U87 glioma cells, in our hands, liquiritigenin displayed an  $IC_{50}$  value of 88.3  $\mu M$  in this assay, whereas all our oxime-based  $ER\beta$ -agonists proved to be more potent than this. In particular, ketoxime **2a**, which was also found to be the most potent  $ER\beta$  agonist in both the reporter (Table 2) and the endogenous (Table 3) gene assays, demonstrated the highest potency as an antiproliferative agent from this series, with an  $IC_{50}$  value of 35.0  $\mu M$ . In addition, since activation of  $ER\beta$  is also known to exert an antiproliferative effect in colorectal and breast tumors,<sup>10</sup> we extended our in vitro screening to colon (LoVo, HCT) and breast (MDA231, MCF7) cancer cell lines. In all these cell lines, oxime derivatives **1**, **2a**, and **2c** still displayed the most potent inhibition of proliferation when compared to liquiritigenin. Finally, we included in our study the  $ER\beta$ -negative breast cancer cell line SkBr3<sup>28</sup> in order to verify the contribution of  $ER\beta$  activation to the antiproliferative effect of these compounds. Notably, the activities of the oxime-based  $ER\beta$  agonists **1**, **2a**, and **2c** against SkBr3 cells were significantly lower than their activities against all the other  $ER\beta$ -positive cancer cells. For a more significant evaluation of the involvement of  $ER\beta$  in the antiproliferative effect of these compounds, we can restrict our comparison to only breast cancer cells. Then the differences in the  $IC_{50}$  values found in  $ER\beta$ -positive MDA231 and MCF7 cells (2.7–16.4  $\mu M$  range) and those in  $ER\beta$ -negative SkBr3 cells (86.3–96.2  $\mu M$ ) are even more evident, with 6- to 34-fold reductions of antiproliferative activities in the  $ER\beta$ -negative cancer cells. Of course, we cannot exclude the involvement of other mechanisms in the inhibition of proliferation by compounds **1**, **2a**, and **2c**, since some activity is also noted in SkBr3 cells. Nevertheless, these results confirm a highly significant involvement of the activation of  $ER\beta$  in the antiproliferative effects of these compounds.

To complete the evaluation of our compounds **1**, **2a**, and **2c** against glioma, we carried out an in vivo study using U87 glioma cells grown as xenografts in nude mice, an in vivo model that has already been used to evaluate the antiglioma effect of liquiritigenin.<sup>8</sup> After tumors reached a measurable size, the indicated compounds (10 mg/kg/mouse/day) were administered for 14 days, and the tumor volume was measured with a caliper. After 14 days of treatment no signs of animal weight loss were observed (see Table S1, Supporting Information). As shown in Figure 7, ketoxime **2a** produced a statistically significant reduction of the tumor volume when compared to control vehicle, whereas the effects of **1** and **2c** were negligible. This is not surprising since compound **2a**, when compared to the other two compounds, displayed the highest  $ER\beta$ -binding

**Figure 7.** Tumor volume (normalized to control, which was set at 1) of subcutaneous implanted U87 cells in nude mice after 14 days of treatment with 10 mg/kg compounds. The values are derived from  $\geq 5$  mice, and bars show SE.

affinity and  $ER\beta$ -transcriptional activation, as well as the most potent antiproliferative activity against U87 cells. Therefore, these in vivo results indicate that our most potent  $ER\beta$ -agonist, **2a**, is effective in reducing the progression of tumor growth in both an in vitro and in vivo model of this glioma.

## CONCLUSION

In summary, molecular modeling studies drove us to the rational design of some new ketoxime derivatives by introducing small alkyl groups on the oxime carbon atom of previously developed salicylaldoxime-based  $ER\beta$  agonists. Some of the newly synthesized compounds displayed remarkably high subtype-selective binding affinities for  $ER\beta$ , which is unprecedented for this chemical class of ligands. In particular, these compounds proved to behave as full agonists on  $ER\beta$  and to activate transcription of reporter genes and endogenous genes, highlighting their very high  $ER\beta$  potency selectivity. Finally, we could then demonstrate that one of these ketoxime derivatives efficiently inhibited tumor progression of  $ER\beta$ -expressing human glioma cells, both in vitro and in vivo. These results further extend the therapeutic potential of  $ER\beta$ -selective agonists.

## EXPERIMENTAL SECTION

**General Procedures and Materials.** All solvents and chemicals were used as purchased without further purification. Chromatographic separations were performed on silica gel columns by flash (Kieselgel 40, 0.040–0.063 mm; Merck) or gravity column (Kieselgel 60, 0.063–0.200 mm; Merck) chromatography. Reactions were followed by thin-layer chromatography (TLC) on Merck aluminum silica gel (60 F<sub>254</sub>) sheets that were visualized under a UV lamp. Evaporation was performed in vacuo (rotating evaporator). Sodium sulfate was always used as the drying agent. Proton (<sup>1</sup>H) and carbon (<sup>13</sup>C) NMR spectra

were obtained with a Varian Gemini 200 MHz spectrometer using the indicated deuterated solvents. Chemical shifts are given in parts per million (ppm) ( $\delta$  relative to residual solvent peak for  $^1\text{H}$  and  $^{13}\text{C}$ ). Electron impact (EI, 70 eV) mass spectra were obtained on a HP-5988A mass spectrometer. High-resolution mass spectrometry (HRMS) analysis was performed using a Waters Quattro II quadrupole–hexapole–quadrupole liquid chromatography/mass spectrometry apparatus (Waters, Milford, MA) equipped with an electrospray ionization source. Purity of the final compounds **2a–m** was determined by high performance liquid chromatography (HPLC) on a Waters SunFire RP 18 (3.0 mm  $\times$  150 mm, 5  $\mu\text{m}$ ) column (Waters, Milford, MA, [www.waters.com](http://www.waters.com)) using a Beckmann System-Gold instrument consisting of chromatography 125 solvent module and a 166 UV detector set at 254 and 300 nm, and injection volume was 30  $\mu\text{L}$  (see below for details about mobile phase and flow rate). The purity was always  $\geq 95\%$ , unless otherwise specified. Yields refer to isolated and purified products derived from nonoptimized procedures.

**Preparation of Ketones 5e–h, 5j, 5l, 6, 7, and 12. General Procedure.** A solution of  $\text{Pd}(\text{OAc})_2$  (50 mg, 0.22 mmol) and triphenylphosphine (294 mg, 1.12 mmol) in ethanol (12 mL) and toluene (12 mL) was stirred at rt under nitrogen for 10 min. After that period, 5.8 mmol of commercially available 5-bromo-2-hydroxyacetophenone (**3**) or 5-bromo-2-hydroxypropiophenone (**4**), a 2 M aqueous solution of  $\text{Na}_2\text{CO}_3$  (13 mL), and the appropriate arylboronic acid (1.2 equiv) were sequentially added. The resulting mixture was heated at 100  $^\circ\text{C}$  in a sealed vial under nitrogen overnight. After being cooled to rt, the mixture was diluted with water and extracted with EtOAc. The combined organic phase was dried and concentrated. The crude product was purified by flash chromatography over silica gel. Elution with *n*-hexane/EtOAc (95:5 to 8:2) afforded the desired ketone intermediates. The same procedure was applied to 1-(5-bromo-2-methoxyphenyl)-2,2,2-trifluoroethanone (**11**), which was synthesized as previously reported.<sup>18</sup>

**Preparation of O-Deprotected Ketones 8a–d, 8i, 8k, and 13. General Procedure.** A solution of pure ketones **5e**, **5f**, **5j**, **5l**, **6**, **7**, and **12** (0.90 mmol) in anhydrous  $\text{CH}_2\text{Cl}_2$  (11 mL) was cooled to  $-78\text{ }^\circ\text{C}$  and treated dropwise with a 1.0 M solution of  $\text{BBr}_3$   $\text{CH}_2\text{Cl}_2$  (3 mL) under nitrogen. The mixture was left under stirring at the same temperature for 5 min and then at 0  $^\circ\text{C}$  for 1 h. The mixture was then diluted with water and extracted with ethyl acetate. The organic phase was dried and concentrated. The crude product was purified by flash chromatography over silica gel. Elution with *n*-hexane/EtOAc (8:2 to 7:3) afforded the desired O-deprotected ketones.

**Preparation of Final Products 2a–m. General Procedure.** A solution of pure ketones **5e–h**, **5j**, **5l**, **8a–d**, **8i**, **8k**, **13** (1.2 mmol) in ethanol (20 mL) was treated with a solution of hydroxylamine hydrochloride (257 mg, 3.72 mmol) in water (4 mL), and the mixture was heated to 50  $^\circ\text{C}$  for 16 h. After being cooled to rt, part of the solvent was removed under vacuum, and the mixture was diluted with water and extracted with EtOAc. The organic phase was dried and evaporated to afford a crude residue that was purified by column chromatography (*n*-hexane/ethyl acetate 7:3) to afford the desired ketoxime derivatives.

**(E)-1-(6-Hydroxy-3-(4-hydroxyphenyl)phenyl)ethanone Oxime (2a).** White solid; yield 50% from **8a**; mp 188  $^\circ\text{C}$ .  $^1\text{H}$  NMR (acetone- $d_6$ )  $\delta$  (ppm): 2.44 (s, 3H), 6.88–6.94 (m, 3H), 7.44–7.52 (m, 3H), 7.70 (d, 1H,  $J = 2.2$  Hz), 8.36 (exchangeable s, 1H), 10.70 (exchangeable s, 1H), 11.45 (exchangeable s, 1H).  $^{13}\text{C}$  NMR (acetone- $d_6$ )  $\delta$  (ppm): 10.80, 116.43 (2C), 117.98, 119.91, 126.32, 128.32 [2C], 129.06, 132.74, 132.83, 157.45, 157.69, 159.18. **Modeling.** The crystal structure of ER $\alpha$  (PDB code 2IOJ) and ER $\beta$  (PDB code 2IOG)<sup>29</sup> was taken from the Protein Data Bank.<sup>30</sup> After addition of hydrogen atoms, the two proteins complexed with their reference inhibitor were minimized using AMBER 9 software<sup>31</sup> and parm03 force field at 300 K. The two complexes were placed in a rectangular parallelepiped water box. An explicit solvent model for water, TIP3P, was used, and the complexes were solvated with a 10 Å water cap. Sodium ions were added as counterions to neutralize the system. Two steps of minimization were then carried out; in the first stage, we kept the protein fixed with a position restraint of 500 kcal/(mol·Å<sup>2</sup>) and we solely minimized the positions of the water molecules. In the second stage, we minimized the entire system through 5000 steps of steepest descent followed by conjugate gradient (CG) until a convergence of 0.05 kcal/(Å·mol). The two ligands were built using Maestro<sup>32</sup> and were minimized by means of MacroModel<sup>33</sup> in a water environment using the CG method until a convergence value of 0.05 kcal/(Å·mol), using the MMFFs force field and a distance-dependent dielectric constant of 1.0. Automated docking was carried out by means of the AUTODOCK 4.0 program;<sup>34</sup> Autodock Tools<sup>35</sup> was used in order to identify the torsion angles in the ligands, add the solvent model, and assign the Kollman atomic charges to the protein. The ligand charge was calculated using the Gasteiger method. In order to prevent the loss of the intramolecular H-bond of the pseudocycle/oxime system, during the docking we blocked the torsions involved in this intramolecular bond. The regions of interest used by Autodock were defined by considering SERBA-1<sup>29</sup> into both receptors as the central group; in particular, a grid of 50, 40, and 46 points in the  $x$ ,  $y$ , and  $z$  directions was constructed centered on the center of the mass of this compound. A grid spacing of 0.375 Å and a distance-dependent function of the dielectric constant were used for the energetic map calculations. By use of the Lamarckian genetic algorithm, the docked compounds were subjected to 100 runs of the

Autodock search, using 500 000 steps of energy evaluation and the default values of the other parameters. Cluster analysis was performed on the results using an rms tolerance of 1.0 Å, and the best docked conformation was used for the analysis. For the docking of compound **2b** into ER $\beta$ , F356 was considered as a flexible residue. The reported docking procedure has recently been indirectly validated by the deposition of the crystal structure of ER $\alpha$  complexed with 2-chloro-3'-fluoro-3-[(*E*)-(hydroxyimino)methyl]biphenyl-4,4'-diol (PDB code 4IWF).<sup>36</sup> Before the deposition of this structure, in 2011 we reported a docking analysis of this compound into ER $\alpha$ ,<sup>13c</sup> superimposing the docking with the experimental results, the proposed binding mode was correctly predicted, as the two compounds showed a root-mean-square deviation of their disposition of 1.0 Å.

**Relative Binding Affinity Assay.** Relative binding affinities were determined by competitive radiometric binding assays with 2 nM [<sup>3</sup>H]E<sub>2</sub> as tracer, as a modification of methods previously described.<sup>20,21</sup> The source of ER was purified full-length human ER $\alpha$  and ER $\beta$  purchased from Pan Vera/Invitrogen (Carlsbad, CA). Incubations were done at 0 °C for 18–24 h, and hydroxyapatite was used to absorb the purified receptor–ligand complexes (human ERs).<sup>21</sup> The binding affinities are expressed as relative binding affinity (RBA) values, where the RBA of estradiol is 100%; under these conditions, the *K*<sub>d</sub> of estradiol for ER $\alpha$  is ~0.2 nM, and for ER $\beta$  it is 0.5 nM. The determination of these RBA values is reproducible in separate experiments with a CV of 0.3, and the values shown represent the average  $\pm$  range or SD of two or more separate determinations.

**Reporter Gene Assays.** The procedures used for the ER $\alpha$  and ER $\beta$ -responsive reporter gene assays in HEC-1 cells have been fully described in prior publications.<sup>22,23</sup>

**Endogenous Gene Assays.** The procedures used for the assay of ER $\alpha$  and ER $\beta$ -responsive endogenous gene in MCF-7 cells containing ER $\alpha$  only, ER $\beta$  only, or ER $\alpha$  + ER $\beta$  have been fully described in prior publications.<sup>24–26</sup>

**Cell Viability Assay.** U87-MG cells were purchased from Sigma and maintained at 37 °C in a humidified atmosphere containing 5% CO<sub>2</sub> accordingly to the supplier. Cells (10<sup>3</sup>) were plated in 96-well culture plates. The day after seeding, vehicle or compounds were added at different concentrations to the medium at a concentration ranging from 1000 to 0.1  $\mu$ M. Cell viability was measured after 96 h according to the supplier (Promega, G7571) with a Tecan F200 instrument. IC<sub>50</sub> values were calculated from logistical dose response curves. Averages and standard errors were obtained from three different experiments.

**Nude Mice.** All animal experiments were approved by the Ethical Committee for Animal Experimentation (CESA) and performed in accordance with the institution guidelines. For xenograft tumor assays, 2  $\times$  10<sup>6</sup> U87 cells were mixed with 30% of Matrigel and implanted subcutaneously into the flanks of 6-week-old female nude mice. Once tumors reached measurable size, mice were treated with specify drug (10 mg/kg) subcutaneously once every other day for 14 days (*n*  $\geq$  5). Tumor volume was measured with a caliper instrument and calculated by using the formula  $\frac{1}{2}(\text{length} \times \text{width}^2)$ . Body weight was measured at weekly intervals to monitor drug toxicity.
