Received October 30, 2009. Revised Manuscript Received January 21, 2010

Shenfu coal (SFC) oxidation with RuO₄ and NaOCl were studied and compared. Most of organic matter in SFC was converted into soluble species with either of the oxidants. Benzene polycarboxylic acids (BPCAs) and alkanoic acids (AAs) are the main products from the reactions. The products from SFC oxidation with RuO₄ are rich in long-chain AAs, whereas those with NaOCl predominantly consist of chloro-substituted short-chain AAs and BPCAs. The related reaction mechanisms are discussed according to the experimental results.

1. Introduction

Coal oxidation is one of the useful methods for understanding coal structure, especially the composition of organic matter in coals.¹⁻⁴ Many attempts have been made for obtaining organic acids from coals by oxidation in alkali or acid solution. 5-7 RuO₄, which is well-known as an effective oxidant for selective degradation of macromolecular network in coals, has been widely used for characterizing the aliphatic and aromatic portions in coals. 8,9 Huang et al. 10 examined the differences in structural features among Shenfu coal (SFC), its liquefaction residue and extraction residue through ruthenium ion-catalyzed oxidation (RICO). A number of alkanoic acids (AAs) and benzene polycarboxylic acids were produced from RICO of SFC and its residues. The resulting carboxylic acids were confirmed to be particularly useful for synthesizing functional material, 11 medicines, 12 and aircraft fuel. 13 Unfortunately, industrial use of RICO is difficult because of its high cost.

SFC is a typical low-rank bituminous coal in China. Because of its very large reserve (223.6 Gt)¹⁴ and very low contents of ash, sulfur, and phosphorus, it is used as one of major power steam coals in China and as a main feedstock for the pilot project of Shenhua coal liquefaction, the largest project for coal hydroliquefaction over the world. 15 Alternative conversions, such as oxidation, of SFC also deserve investigating.

Because of its easy availability, environmental friendliness, and electrolytic renewability, ¹⁶ NaOCl is attractive as an industrial oxidant. In addition, it is highly reactive toward coal oxidative degradation. ¹⁷⁻²⁰ In the present study, we investigated SFC oxidation with RuO4 and NaOCl, respectively, to understand the difference between the two oxidants for coal oxidation and to find a potential way for obtaining organic acids from coals.

2. Experimental Section

- 2.1. Coal Sample and Reagents. SFC, collected from Shenmu-Fugu coal field, Shaanxi, China, was pulverized to pass through a 200-mesh screen and dried in a vacuum at 80 °C for 24 h before use. Table 1 shows the proximate and ultimate analyses of the coal sample. RuCl₃, NaIO₄, CH₂N₂, (CH₃CH₂)₂O, CH₃CN, CCl₄, CH₂Cl₂, HCl, NaOCl (6% available chlorine), and anhydrous MgSO₄ used in the experiments are analyticalpure reagents, and all the organic solvents were distilled before
- **2.2. Main Instruments.** A Büchi R-134 rotary evaporator was used for distillation of solvents from the reaction mixture. The instruments for quantitative and qualitative analyses of products are a Nicolet Magna IR-560 Fourier transform infrared

 a daf = dry and ash-free base; $M_{\rm ad}$ = moisture (air dried base); $A_{\rm d}$ = ash (dry base, i.e., moisture-free base); $V_{\rm daf}$ = volatile matter (dry and ash-free base).

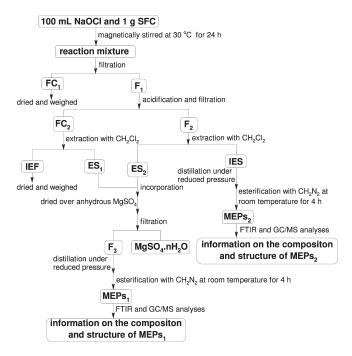

Figure 1. Procedure for SFC oxidation with NaOCl, subsequent treatment, and product analyses.

(FTIR) spectrometer and a Hewlett-Packard 6890/5973 gas chromatography/mass spectrometer (GC/MS) equipped with a capillary column coated with HP-5 (cross-link 5% PH ME siloxane, 30 m \times 0.25 mm i.d., 0.25 μ m film thickness) and a quadrupole analyzer and operated in electron impact (70 eV) mode.

2.3. Oxidation, Subsequent Treatment, and Product Analyses. The oxidation of SFC with RuO₄ was carried out according to a reported procedure. ¹⁰ SFC (0.4 g) was added to a mixture of RuCl₃ (20 mg), CH₃CN (20 mL), CCl₄ (20 mL), and distilled water (30 mL). With rapid stirring, NaIO₄ (8 g) was added and the mixture was stirred for 36 h at 35 °C. Then the solid was separated by filtration followed by phase separation of the filtrate to afford the aqueous solution and the organic solution. Both the filter cake and aqueous solution were extracted with CH₂Cl₂. The extraction solutions and the above organic solution were incorporated and dried over anhydrous MgSO₄. After removal of the solvents from the dried solution with a rotary evaporator under reduced pressure, the products were esterified with excess CH₂N₂ in (CH₃CH₂)₂O followed by FTIR and GC/MS analyses.

As Figure 1 shows, SFC (1 g) and NaOCl aqueous solution (100 mL) were added to a 250 mL spherical flask and fully mixed by magnetically stirring at 30 °C for 24 h. The reaction mixture was filtrated to afford a filter cake (FC₁) and filtrate (F₁). The FC₁ was dried in a vacuum at 80 °C for 24 h and then weighed. The F₁ was acidified to pH 2–3 to convert –COONa to –COOH in the reaction products and filtrated to afford the filter cake (FC₂) and filtrate (F₂). Both FC₂ and F₂ were extracted with CH₂Cl₂. Then, the extraction solutions (ES₁ and ES₂) were incorporated. The incorporated solution was dried over anhydrous MgSO₄ and filtrated to remove MgSO₄ · nH₂O.

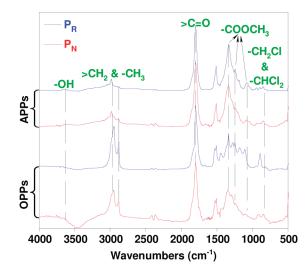

Figure 2. FTIR spectra of the methyl esterified products from SFC oxidation with RuO₄ and NaOCl.

After removal of CH_2Cl_2 from the filtrate (F_3) with a rotary evaporator under reduced pressure, the reaction products were esterified with excess CH_2N_2 in $(CH_3CH_2)_2O$ to afford methyl esterified products $(MEPs_1)$. The CH_2Cl_2 -inextractable fraction (IEF) from FC_2 , which was defined as black acid, ²⁰ was also dried and weighed. Water and a small amount of CH_2Cl_2 in the CH_2Cl_2 -inextractable solution (IES) from F_2 were removed with a rotary evaporator under reduced pressure followed by esterification with CH_2N_2 in $(CH_3CH_2)_2O$ to afford the corresponding methyl esterified products $(MEPs_2)$. Both $MEPs_1$ and $MEPs_2$ were analyzed with FTIR and GC/MS.

The mass range scanned was from 30 to 500 amu. Data were acquired and processed using Chemstation software. The compounds were identified by comparing the mass spectra with NIST05a library data. Quantitative analyses were also conducted on the basis of parent SFC mass with GC/MS using a series of authentic compounds as external standards, e.g., methyl caproate for monocarboxylic acids (MCAs), dimethyl adipate for dicarboxylic acids (DCAs) and tricarboxylic acids, and dimethyl phthalate for benzene carboxylic acids (BCAs).

3. Results and Discussion

After oxidation with NaOCl for 24 h, the yields of FC_1 and IEF were only 2% and 12%, respectively, based on organic matter in SFC, indicating that most of organic matter in SFC was converted to water-soluble species. However, quantifying the insoluble fraction from SFC oxidation with RuO_4 is difficult because an uncertain amount of insoluble $NaIO_3$ was formed during the oxidation.

For convenience in description, the methyl esterified products from SFC oxidation with RuO_4 and with NaOCl are denoted as P_{RuO4} and P_{NaOCl} , respectively, and total ion chromatograms are denoted as TICs.

3.1. FTIR Analysis. As Figure 2 displays, almost no absorbance at 3730 cm $^{-1}$ is observed, but those at 1268, 1197, and 1004 cm $^{-1}$ are very strong, suggesting that most of -COOH in the products was converted to $-\text{COOCH}_3$ by esterification with CH_2N_2 . For both P_{RuO4} and P_{NaOCI} , the absorbances at 2929 and 2842 cm $^{-1}$ attributed to the aliphatic moiety (AM) in organic phase products (OPPs) are much stronger than those in aqueous phase products (APPs), indicating that most of the AM-rich components were

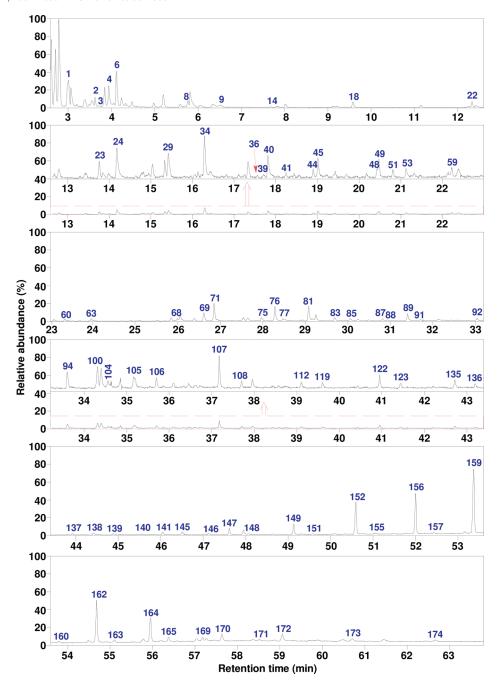

Figure 3. TICs of the methyl esterified products in the organic phase from SFC oxidation with RuO₄.

extracted by organic solvent. Besides, the absorbances at 2929 and 2842 cm $^{-1}$ in P_{RuO4} are appreciably stronger than those in P_{NaOCl} , suggesting that more AM-containing products were formed via SFC oxidation with RuO_4 than with NaOCl. The existence of $-CH_2Cl$ and $-CHCl_2$ can be seen from the absorbance at 745 cm $^{-1}$ both in P_{RuO4} and in P_{NaOCl} , but the absorbance in P_{NaOCl} is significantly stronger than that in P_{RuO4} , implying that chlorine in the NaOCl aqueous solution was involved in the reaction.

3.2. GC/MS Analysis. As exhibited in Figures 3–6, in total, 174 methyl esterified products were identified by GC/MS analysis and their parent ones can be classified into MCAs, DCAs, BCAs, hydrocarbons (HCs), and others species (OSs). These products can also be divided into organochlorine compounds (OCCs) and nonorganochlorine compounds (NOCCs).

As listed in Tables 2 and 3, 34 AAs and 22 chlorosubstituted AAs (CSAAs) were detected in total. In total 32 AAs and only 3 CSAAs (i.e., chloroacetic acid, dichloroacetic acid, and trichloroacetic acid) appeared in $P_{\rm RuO4}$. In contrast, all of the 22 CSAAs were detected in $P_{\rm NaOCl}$, and most of them are α -chloro-substituted MCAs. In addition, long-chain AAs (carbon number > 17) are rich in $P_{\rm RuO4}$ but were not detected in $P_{\rm NaOCl}$.

As illustrated in Figure 7, the yield of MCAs in P_{RuO4} is much lower than that in P_{NaOCl} . Most of MCAs detected in P_{NaOCl} are OCCs, but OCCs only account for $\sim 36\%$ MCAs detected in P_{RuO4} . In P_{NaOCl} , trichloroacetic acid (peak 17 in Figure 6) is the most abundant, accounting for $\sim 50\%$ of MCAs, while $\sim 25\%$ of MCAs is dichloroacetic acid (peak 8 in Figure 6). These facts indicate that SFC itself contains OCCs as reported previously, 21 but chlorine

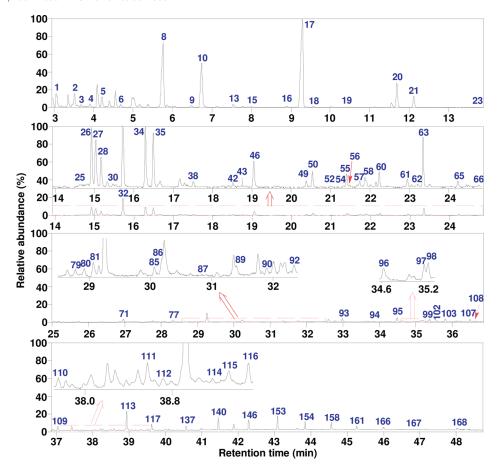

Figure 4. TICs of the methyl esterified products in the organic phase from SFC oxidation with NaOCl.

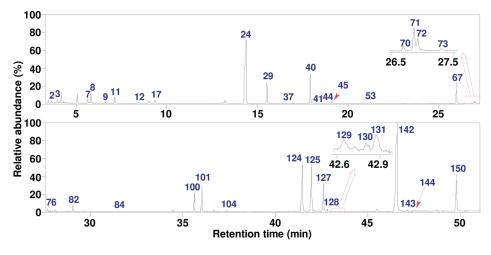

Figure 5. TICs of the methyl esterified products in the aqueous phase from SFC oxidation with RuO₄.

in most of the OCCs from P_{NaOCl} resulted from NaOCl. No OCCs were detected in DCAs, BCAs, and OSs from P_{RuO4} , whereas $\sim 38\%$ of DCAs, $\sim 21\%$ of BCAs, and almost all the OSs are OCCs. In addition, the yields of MCAs and HCs in P_{NaOCl} are much higher than those in P_{RuO4} , but the yields of DCAs, BCAs, and OSs in P_{NaOCl} are significantly lower than those in P_{RuO4} . The above significant differences suggest that the mechanism for SFC

oxidation with RuO₄ is quite different from that with N₂OCl

In total 36 alkane- α , ω -dicarboxylic acids (ADCAs) and 6 chloro-substituted ADCAs (CSADCAs) were detected in the products from SFC oxidation, as listed in Tables 4 and 5, respectively. All the ADCAs appear in P_{RuO4} , but there are only 8 ADCAs in P_{NaOCI} . In contrast, P_{NaOCI} contains all the CSADCAs, but no CSADCAs are contained in P_{RuO4} . Similar to the case of MCAs, long-chain ADCAs were only detected in P_{RuO4} .

As Tables 6 and 7 list, in total 22 BCAs and 30 chlorosubstituted BCAs (CSBCAs) were yielded. The BCAs include

Table 8 lists 16 HCs, including 4 arenes and 12 alkanes, detected in the products from SFC oxidation. All the arenes were detected both in P_{RuO4} and in P_{NaOCl} with almost the same yield. All the alkanes were detected in P_{NaOCl} , but only 3 alkanes with much lower yields were found in P_{RuO4} .

OSs detected in the products from SFC oxidation include 3 OCCs and 5 tricarboxylic acids, as shown in Table 9. All the 3 OCCs were detected in $P_{\rm NaOCl}$, but no OCCs were found in

RuO₄ selectively oxidizes aromatic units to carboxylic acids such as AAs, alkanedioic acids, and BCAs, as demonstrated in Scheme 1. However, only a few researchers paid attention to the mechanism for coal oxidation with NaOCl. Different from RuO₄, NaOCl was reported to oxidize the side chain on the benzene ring rather than the benzene ring itself, as illustrated in Scheme 2.¹⁷ Some polynuclear aromatics can be oxidized with NaOCl to BCAs, especially in the presence of either phenolic or carboxylic functional groups on the polynuclear aromatic rings. ¹⁹ For example, naphthalene was reported to be reactive toward oxidation with NaOCl to selectively afford phthalic acid.²⁵ These results and proposals can interpret the formation of MCAs, DCAs, and BCAs to some extent, but there are still some questions that need to be answered. The questions are related to the reasons for a much higher total yield of MCAs in P_{NaOCl} than that in P_{RuO4}, the mechanisms for the formation of short-chain

concluded that the resorcinol-type moiety of fulvic acids yields dichloroacetic acid, trichloroacetic acid, and other α -chloro-substituted MCAs during the oxidation. The resorcinol-type moiety contained in coals may not be as rich as in fulvic acids. We found that phenol oxidation with NaOCl yielded methyl 2,2,3,3-tetrachloropropanoate and

ethyl 2,2,2-trichloroacetate as the main products along with a much smaller amount of methyl 2-chloroacetate, methyl 2,2-dichloroacetate, ethyl 2,2-dichloroacetate, methyl 2,2,2-trichloroacetate, and methyl 2,3,3-trichloroacrylate as byproducts (Figure SI-1 in the Supporting Information). These compounds are also relatively abundant in P_{NaOCl}. Hence, we suppose that most of the short-chain CSAAs detected in P_{NaOCl} were produced from the phenolic moiety of SFC during its oxidation. We also examined 1,3-diphenylpropane oxidation with NaOCl and found that a series of long-chain alkanes were formed during the oxidation (Figure SI-2 in the Supporting Information), although the related mechanism remains unclear. This fact corroborates that most of the alkanes were produced from the oxidation of α, ω -diarylalkanes in SFC with NaOCl.

4. Conclusions

Most of organic matter in Shenfu coal was converted into soluble species through oxidation with either RuO_4 or NaOCl. The products from the oxidation of Shenfu coal with NaOCl are more complex and contain much more chloro-substituted species than those with RuO_4 , while the soluble species obtained with RuO_4 are rich in long-chain alkanoic acids and alkane- α , ω -dicarboxylic acids, but those with NaOCl consist of considerable amounts of short-chain chloro-substituted alkanoic acids and alkanes. Most of the short-chain chloro-substituted alkanoic acids were confirmed to be derived from the phenolic moiety of Shenfu coal, while α , ω -diarylalkanes could be precursors of some alkanes.

NaOCl is expected to be an industrial oxidant for obtaining organic acids from coals due to its easy availability, environmental friendliness, and electrolytic renewability, but optimization of reaction conditions, such as molar ratio of NaOCl to coal, reaction temperature and time, and pH value, is needed for inhibiting side-reactions, especially chlorination.
